## The KCFSI suggests financial stress edged down in December but remained above its long-run average.

The Kansas City Financial Stress Index (KCFSI) was 0.21 in December, down slightly from 0.26 in November. December's decline followed a steeper drop in November. Despite the decrease, the KCFSI remained above its long-run average of zero for the fifth consecutive month.

Four of the eleven variables making up the KCFSI decreased from November to December, while five variables increased. Changes in measures of yield spreads increased the KCFSI by a total of 0.05 point, while changes in asset price behavior decreased the index by 0.10 point. The variables with the greatest negative contributions to the change in the KCFSI were the implied volatility of overall stock prices (VIX), which subtracted 0.11 point, and the correlation between stock and Treasury returns, which deducted 0.03 point. The variable with the biggest positive contribution was the idiosyncratic volatility of bank stock prices, which added 0.04 point.

### KCFSI, 1990-2011

### KCFSI, Dec-08 to Dec-11

| Cross-section dispersion of bank stock returns   | -0.01                           | 4                              |
| <b>Total</b>   | <b>-0.05</b>                    |                                |
| Note: The contribution of each variable equals the change in the standardized value of the variable times the coefficient of the variable in the index. Contributions may not add to totals due to rounding. |                                 |                                |

## Frequently Asked Questions

**What is the KCFSI?** The KCFSI is a monthly composite index of 11 variables reflecting stress in the U.S. financial system. These variables fall into two broad categories--average yield spreads, and measures based on the actual or expected behavior of asset prices. The index is calculated using the principal components procedure. Under this procedure, the coefficients of the 11 variables are chosen so that the index explains the maximum possible amount of total variation in the variables from February 1990 through the current month. Further details on the variables and the construction of the index can be found in Section II of “Financial Stress: What Is It, How Can It Be Measured, and Why Does It Matter?” by Craig S. Hakkio and William R. Keeton, *Economic Review*, Federal Reserve Bank of Kansas City, Second Quarter 2009.

**Why are past values of the index sometimes revised?** Most revisions are due to recalculating the index using the additional data from the current month. These revisions are inherent in the principal components procedure and are explained in more detail in Appendix B of the article by Hakkio and Keeton. Other changes in past values of the index may result from revisions to the data used to construct the variables. Finally, the index may occasionally be revised due to a change in the data sources or in the method of constructing a variable. In this last case, an explanation for the revision is included in the monthly summary.

**How should the index be interpreted?** A positive value of the KCSFI indicates that financial stress is above the long-run average, while a negative value signifies that financial stress is below the long-run average. A useful way to assess the level of financial stress is to compare the index in the current month to the index during a past, widely-recognized episode of financial stress, such as October 1998. For more information on interpreting the index, see Section III of the article by Hakkio and Keeton.
