The Kansas City Financial Stress Index (KCFSI) decreased from -0.51 in January to -0.61 in February.

The second table on the following page documents the contribution of each variable to the index. Yield spreads collectively added 0.07 to the KCFSI in February. The behavior of asset prices subtracted 0.17 from the KCFSI in February.

Note: The contribution of each variable equals the change in the standardized value of the variable multiplied by the coefficient of the variable in the index. Contributions may not add to totals due to rounding.

---

¹ The off-the-run/on-the-run 10-year Treasury spread for February 2017 is based on data through February 24 due to availability.

² The Aaa/10-year Treasury spread for February 2017 is based on data through February 24 due to availability.
**Frequently Asked Questions**

**What is the KCFSI?** The KCFSI is a monthly composite index of 11 variables reflecting stress in the U.S. financial system. These variables fall into two broad categories--average yield spreads, and measures based on the actual or expected behavior of asset prices. The index is calculated using the principal components procedure. Under this procedure, the coefficients of the 11 variables are chosen so that the index explains the maximum possible amount of total variation in the variables from February 1990 through the current month. Further details on the variables and the construction of the index can be found in Section II of “Financial Stress: What Is It, How Can It Be Measured, and Why Does It Matter?” by Craig S. Hakkio and William R. Keeton, *Economic Review*, Federal Reserve Bank of Kansas City, Second Quarter 2009.

**Why are past values of the index sometimes revised?** Most revisions are due to recalculating the index using the additional data from the current month. These revisions are inherent in the principal components procedure and are explained in more detail in Appendix B of the article by Hakkio and Keeton. Other changes in past values of the index may result from revisions to the data used to construct the variables. Finally, the index may occasionally be revised due to a change in the data sources or in the method of constructing a variable. In this last case, an explanation for the revision is included in the monthly summary.

**How should the index be interpreted?** The KCFSI is constructed to have a mean value of zero and a standard deviation of one. A positive value of the KCFSI indicates that financial stress is above the long-run average, while a negative value signifies that financial stress is below the long-run average. A useful way to assess the level of financial stress is to compare the index in the current month to the index during a previous episode of financial stress, such as October 2008. For more information on interpreting the index, see Section III of the article by Hakkio and Keeton.
